Fe-SiO<sub>2</sub> catalysts for direct methane reforming were investigated. Low Fe-loading catalysts showed low activity; most of Fe formed inactive Fe silicate. The addition of NiO into Fe-SiO<sub>2</sub> significantly improved the activity.

Key words: methane, direct reforming, Fe catalyst, silica support.

### 1. INTRODUCTION

As hydrogen is a clean gas fuel, the demand for it is steadily increasing.<sup>1</sup> An ideal source of hydrogen is methane CH<sub>4</sub>, because of its large abundance and the highest H/C ratio among saturated hydrocarbons.

Hydrogen is currently produced by steam reforming, partial oxidation and auto-thermal reforming of hydrocarbons, but CO<sub>2</sub> is also produced as by-product.<sup>2</sup>

On the other hand, a direct methane reforming reaction enables us to convert methane to hydrogen without CO<sub>2</sub> emission.<sup>3-4</sup>

Fortunately, the by-product of the direct reforming of methane is mainly carbon nanofibers, a material that has an array of potential applications as electronic components, as polymer additives, and as catalysts/catalyst supports.<sup>5</sup>

The direct reforming of methane are catalyzed by Fe, Co, and Ni supported on hard-reduced metal oxides such as SiO<sub>2</sub>, Al<sub>2</sub>O<sub>3</sub>, and MgO.<sup>6-14</sup>

Of those Ni has been extensively investigated. Takenaka et al.<sup>15</sup> examined the effect of different catalyst supports, such as MgO, Al<sub>2</sub>O<sub>3</sub>, SiO<sub>2</sub>, TiO<sub>2</sub> and ZrO<sub>2</sub>, on the Ni activity for methane reforming, reporting that silica was one of the most effective supports studied. However, yields of hydrogen and carbon nanofibers by supported Ni catalysts decreased significantly with the rise of reaction temperatures of methane decomposition.<sup>15</sup>

On the other hands, Fe-based catalysts have been used at temperatures<sup>16-18</sup> higher than those for Ni-based catalysts. Generally, SiO<sub>2</sub>, Al<sub>2</sub>O<sub>3</sub>, TiO<sub>2</sub>, and ZrO<sub>2</sub> are used as supports of Fe.<sup>19-20</sup> Takenaka et al.<sup>21</sup> investigated a direct methane reforming over Fe<sub>2</sub>O<sub>3</sub>/Al<sub>2</sub>O<sub>3</sub> and Fe<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub> (77 wt% as Fe<sub>2</sub>O<sub>3</sub>) at 1073 K and revealed that the carbon yield for Fe<sub>2</sub>O<sub>3</sub>/Al<sub>2</sub>O<sub>3</sub> (22.5 g-C/g-Fe) was greater than that for Fe<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub> (7.5 g-C/g-Fe). The difference of the catalytic performance between the two catalysts was ascribed to the particle size of the catalytically active iron species. This findings remind us that an interaction between iron metal and its support is crucial for the activity of catalysts, especially supported iron catalysts for the direct reforming of methane.

Supported metal catalysts have been mostly prepared by the conventional impregnation method and those for the direct reforming of methane also without exception.

Alternative method for the preparation of catalysts for this reaction could improve the above interaction. Thus there seems to be still a room for improvement of silica supported Fe catalyst for the direct methane reforming.

In this work, the effects of supports, catalyst preparation methods on the activity of Fe-based catalysts were investigated. In addition, the influence of a small quantity of NiO into Fe<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub> physically mixed catalysts was studied.

### 2. EXPERIMENTAL

#### 2.1 Preparation of catalyst

##### 2.1.1 SiO<sub>2</sub> supported Fe catalyst:

SiO<sub>2</sub>-supported Fe catalysts (Fe/SiO<sub>2</sub>) were prepared by impregnating SiO<sub>2</sub> (SIO-6) with an aqueous solution containing Fe cation. Fe(NO<sub>3</sub>)<sub>3</sub>·9H<sub>2</sub>O was used as Fe precursor. The impregnated sample was dried over night at 100 °C and then calcined for 5 h at 500 °C in air.

##### 2.1.2 Fe<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub> mixed catalysts:

Fe<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub> mixed catalysts (Fe<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub>) were prepared by mixing Fe<sub>2</sub>O<sub>3</sub> with SiO<sub>2</sub> (SIO-6) using a planetary ball mill for 15 minutes.

#### 2.2 Activity tests

The direct methane reforming reaction was carried out at 750 °C using a flow-type fixed-bed tubular reactor made from quartz (an inner diameter and length 2.5 and 70 cm, respectively) by passing pure methane over the catalysts at 30ml/min. In order to reduce Fe precursors to Fe metal, prior to the activity tests, all catalysts were subjected to a reduction pre-treatment using methane (30 ml/min) at temperatures increasing continuously from 20 °C to 750 °C with the rate of 10 °C/min.

The composition of the outlet gas from the reactor was determined by gas chromatography using activated carbon column and a TCD detector. Conversion of methane was evaluated from the amounts of hydrogen formed, assuming that the reaction, CH<sub>4</sub> = C + 2H<sub>2</sub>, occurs selectively. In fact, hydrogen only was detected as a gaseous product.

#### 2.3 Characterization of the catalysts

X-ray diffraction (XRD) patterns of the catalyst samples were measured by a Rigaku RINT-1200 diffractometer using Cu-K $\alpha$  radiation at room temperature. The scanning rate was 4.0 degree/min.

### 3. RESULTS AND DISCUSSION

#### 3.1 Fe/SiO<sub>2</sub> catalysts

Figure 1 shows the effect of percentage fraction by weight of Fe in Fe/SiO<sub>2</sub> catalysts on the activity for DMR. The 20.0%-loading catalyst was inactive and the 40.0%-loading catalyst was slightly active. The percentage conversion of methane did not reach 30% until the percentage fraction of Fe was raised to 67.7%. On the other hand, in the case of Fe/Al<sub>2</sub>O<sub>3</sub>, not only a 40.0%-loading catalyst but also a 20.0%-loading catalyst was quite active (not shown). A 30.0%-loading catalyst was active; the percentage conversion of methane reached 67% (not shown). The results that the activity of Fe/Al<sub>2</sub>O<sub>3</sub> was higher than that of Fe<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub>, in accord with the findings by Takenaka et al.,<sup>8</sup> suggest that an interaction between Fe and its support greatly affect the respective catalysts.

Figure 2 shows the powder XRD patterns of the Fe/SiO<sub>2</sub> catalysts used for the reaction. The 20.0%-loading catalyst contained not Fe metal but Fe silicate, while the 40.0%-loading catalyst contained a small amount of Fe metal together with Fe silicate and Fe<sub>3</sub>C. In the case of the 67.7%-loading catalyst, the contents of Fe metal and

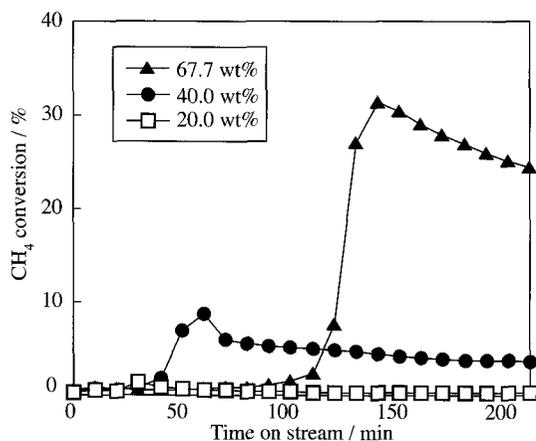

Fig. 1 The activity of Fe/SiO<sub>2</sub> catalysts for direct methane reforming at 750 °C.

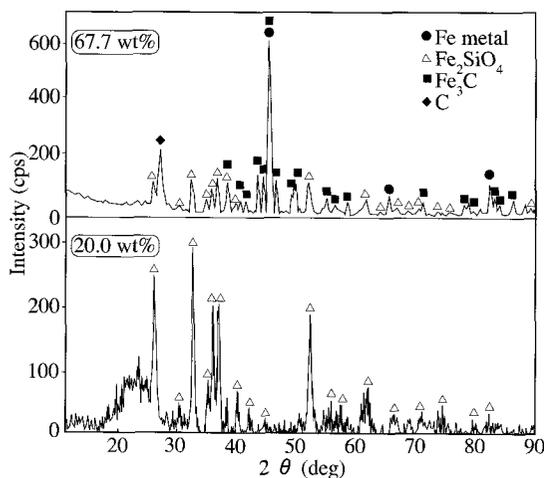

Fig. 2 The powder XRD patterns of the Fe/SiO<sub>2</sub> catalysts used for the reaction.

Fe<sub>3</sub>C increased, while that of Fe silicate almost remained.

In the case of Fe/Al<sub>2</sub>O<sub>3</sub>, even a 20.0%-loading catalyst formed no Fe aluminate; there was Fe metal and Fe<sub>3</sub>C found (not shown). In other words, an interaction between Fe metal and SiO<sub>2</sub> in Fe/SiO<sub>2</sub> was confirmed to be very strong compared to that in Fe/Al<sub>2</sub>O<sub>3</sub>.

Since 20.0%-loading Fe/SiO<sub>2</sub> which has not Fe metal but Fe silicate was inactive, Fe silicate is found to be catalytically inactive. It is clear that active iron species is Fe metal, because all active Fe-based catalysts involved Fe metal as shown above.

#### 3.2 Fe<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub> catalysts

Figure 3 shows the effect of percentage fraction by weight of Fe in Fe<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub> catalysts on the activity. Although the 25.9%-loading catalyst was also inactive, the 40.0%-loading catalyst was highly active; the methane conversion was apparently higher than that of 40.0%-loading Fe/SiO<sub>2</sub>. In the case of 67.7%-loading, Fe<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub> catalyst was much higher than Fe/SiO<sub>2</sub>.

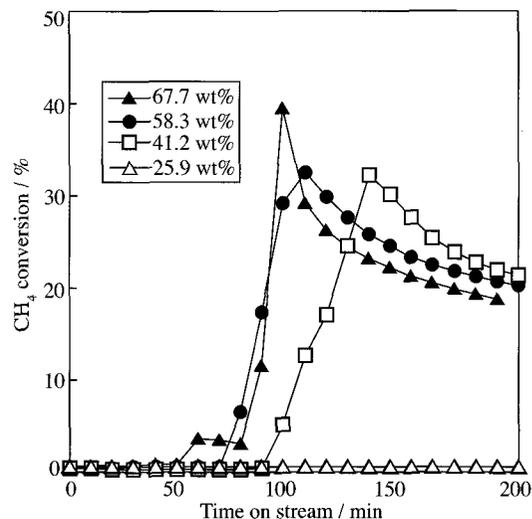

Fig. 3 The activity of Fe<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub> catalysts for direct methane reforming at 750 °C.

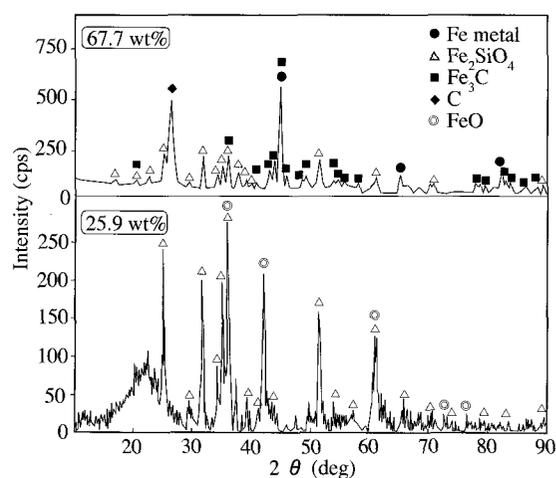

Fig. 4 The powder XRD patterns of the Fe<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub> catalysts used for the reaction.

Figure 4 shows the powder XRD patterns of the  $\text{Fe}_2\text{O}_3\text{-SiO}_2$  catalysts used for the reaction. The 25.9%-loading catalyst contained FeO and Fe silicate, while the 40.0% and more-loading catalyst contained considerable amount of Fe and  $\text{Fe}_3\text{C}$ . The amounts of those components increased with Fe loading but that of Fe silicate remained. The reason the 25.9%-loading  $\text{Fe}_2\text{O}_3\text{-SiO}_2$  was inactive is because it had no Fe metal.

### 3.3 Preparation method of Fe-SiO<sub>2</sub> catalysts

A comparison of Fig. 1 and Fig. 3 shows that the activity of a Fe/SiO<sub>2</sub> catalyst is lower than that of a  $\text{Fe}_2\text{O}_3\text{-SiO}_2$  catalyst having comparable Fe loading.

A detailed comparison of the XRD pattern of 40.0%-loading Fe/SiO<sub>2</sub> and that of 41.2%-loading  $\text{Fe}_2\text{O}_3\text{-SiO}_2$  in Fig. 5 shows that the ratio of the height of the main peak assignable to Fe to that assigned to Fe silicate for the Fe/SiO<sub>2</sub> is lower than that for the  $\text{Fe}_2\text{O}_3\text{-SiO}_2$ . This suggests that an interaction between Fe and SiO<sub>2</sub> in Fe/SiO<sub>2</sub> is stronger than that in  $\text{Fe}_2\text{O}_3\text{-SiO}_2$ . Similar tendency was also confirmed for respective 67.7%-loading catalysts. Therefore, the lower activity of a Fe/SiO<sub>2</sub> compared to a  $\text{Fe}_2\text{O}_3\text{-SiO}_2$  having comparable Fe loading will be ascribed to the stronger interaction of Fe with SiO<sub>2</sub>; the stronger the interaction, the lower the content of catalytically active Fe.

Either 20.0%-loading Fe/SiO<sub>2</sub> or 25.9%-loading  $\text{Fe}_2\text{O}_3\text{-SiO}_2$  contained no Fe. This is the reason why both catalysts showed no activity. However, there is considerable difference in XRD pattern between those: The 20.0%-loading Fe/SiO<sub>2</sub> contained Fe silicate, while 25.9%-loading  $\text{Fe}_2\text{O}_3\text{-SiO}_2$  contained not only Fe silicate but also FeO. The presence of FeO gives evidence that the interaction of Fe with SiO<sub>2</sub> in Fe/SiO<sub>2</sub> is rather weak.

The fact that 20.0%-loading Fe/SiO<sub>2</sub> was inactive but 40.0% or more-loading Fe/SiO<sub>2</sub> was active suggests that the amount of Fe which can react with SiO<sub>2</sub> to form Fe silicate is limited, and so excess amount of Fe can behave as catalytically active species.

Takenaka et al.<sup>21</sup> assumed that  $\text{Fe}_3\text{C}$  as well as  $\alpha\text{-Fe}$  metal are the catalytically active species and the decomposition of  $\text{Fe}_3\text{C}$  into  $\alpha\text{-Fe}$  and carbons produced filamentous carbons, as proposed by several research

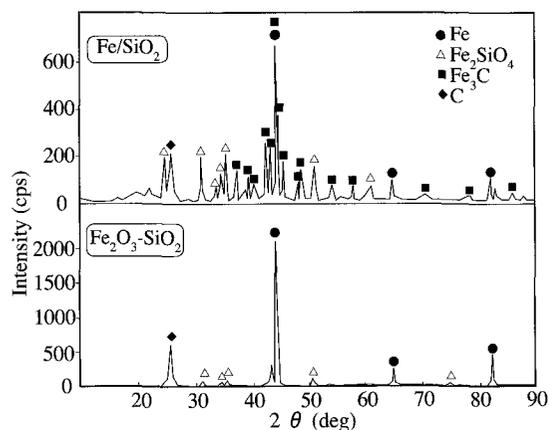

Fig. 5 The powder XRD patterns of the Fe(40.0 wt%)/SiO<sub>2</sub> catalyst and  $\text{Fe}_2\text{O}_3$ (41.2 wt%)-SiO<sub>2</sub> catalyst used for the reaction.

groups.<sup>19, 22</sup>

This explanation holds true for our results that  $\text{Fe}_3\text{C}$  is found together with  $\alpha\text{-Fe}$  in most active Fe-based catalysts.

### 3.4 Addition of NiO to $\text{Fe}_2\text{O}_3\text{-SiO}_2$ catalysts

Figure 6 shows that the activity of  $\text{Fe}_2\text{O}_3\text{-SiO}_2$  was remarkably enhanced by the addition of a small amount of NiO (0.1 g or 0.05 g): The induction period was greatly shortened, the maximum conversion of methane was increased and besides, the significant decrease in activity with respect to time on stream was improved. Regarding binary oxide catalysts,  $\text{Fe}_2\text{O}_3\text{-SiO}_2$  and NiO-SiO<sub>2</sub> were active but  $\text{Fe}_2\text{O}_3\text{-NiO}$  inactive contrary to expectation.

The remarkable change of the induction period due

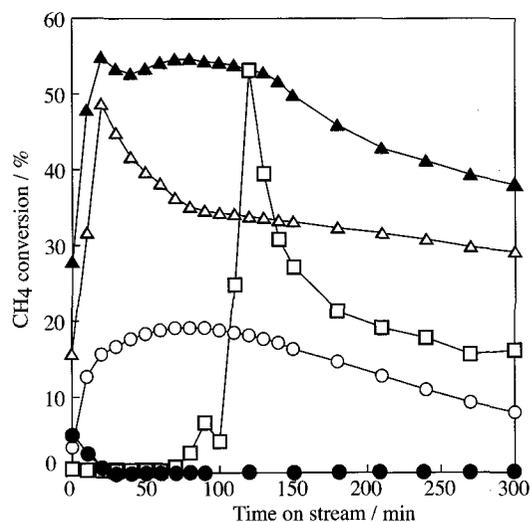

Fig. 6 The activity of  $\text{Fe}_2\text{O}_3\text{-NiO-SiO}_2$  for direct methane reforming at 750 °C.  $\blacktriangle$ :  $\text{Fe}_2\text{O}_3$ (0.4 g)-NiO(0.1 g)-SiO<sub>2</sub>(0.1 g);  $\triangle$ :  $\text{Fe}_2\text{O}_3$ (0.4 g)-NiO(0.05 g)-SiO<sub>2</sub>(0.1 g);  $\square$ :  $\text{Fe}_2\text{O}_3$ (0.4 g)-SiO<sub>2</sub>(0.1 g);  $\circ$ : NiO(0.1 g)-SiO<sub>2</sub>(0.1 g);  $\bullet$ :  $\text{Fe}_2\text{O}_3$ (0.4 g)-NiO(0.1 g).

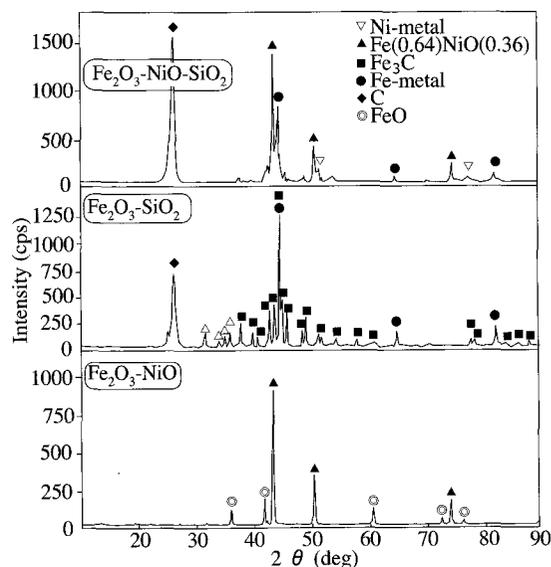

Fig. 7 The powder XRD patterns of  $\text{Fe}_2\text{O}_3$ (0.4 g)-NiO(0.1 g)-SiO<sub>2</sub>(0.1 g),  $\text{Fe}_2\text{O}_3$ (0.4 g)-SiO<sub>2</sub>(0.1 g) and  $\text{Fe}_2\text{O}_3$ (0.4 g)-NiO(0.1 g) catalysts used for the reaction.

to the addition of NiO could be caused by the easier reduction of Fe<sub>2</sub>O<sub>3</sub> to Fe because of abundant hydrogen gas formed by the DMR over Ni metal which is produced earlier than Fe metal, as will be demonstrated elsewhere.<sup>23</sup>

### 3.5 XRD profile of Fe<sub>2</sub>O<sub>3</sub>-NiO-SiO<sub>2</sub> catalyst

Figure 7 shows the powder XRD patterns of both Fe<sub>2</sub>O<sub>3</sub>-NiO-SiO<sub>2</sub> and Fe<sub>2</sub>O<sub>3</sub>-NiO that were used for the reaction.

The XRD patterns revealed that Fe<sub>2</sub>O<sub>3</sub>-NiO-SiO<sub>2</sub> catalysts had both Fe metal and Ni metal together with Fe-Ni alloy; there was no Fe silicate. NiO-SiO<sub>2</sub> that was active contained Ni metal; no Ni silicate was formed. Fe<sub>2</sub>O<sub>3</sub>-NiO having no activity involved Fe-Ni alloy and FeO, indicating that Fe-Ni alloy is inactive, because FeO has been already known to be inactive.

### 3.6 Role of NiO in Fe<sub>2</sub>O<sub>3</sub>-NiO-SiO<sub>2</sub> catalysts

The NiO addition to Fe<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub> prevented the formation of Fe silicate. This can be explained as follows: catalytically inactive Fe-Ni alloy could lie between Fe metal and SiO<sub>2</sub> and disturb their direct contact.

The activity of Fe<sub>2</sub>O<sub>3</sub>-NiO-SiO<sub>2</sub> will be essentially ascribed to the Fe metal and Ni metal.

## 4. Conclusion

On the basis of the results described above, we concluded as follows;

1. The activity of Fe<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub> for the direct methane reforming was higher than that of Fe/SiO<sub>2</sub>. The content of Fe silicate formed in Fe<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub> during the reaction was lower than that in Fe/SiO<sub>2</sub>.
2. The activity of Fe/Al<sub>2</sub>O<sub>3</sub> and Fe<sub>2</sub>O<sub>3</sub>-Al<sub>2</sub>O<sub>3</sub> for the direct methane reforming was higher than those of Fe/SiO<sub>2</sub> and Fe<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub>, respectively. No Fe aluminate was formed in Fe/Al<sub>2</sub>O<sub>3</sub> and Fe<sub>2</sub>O<sub>3</sub>-Al<sub>2</sub>O<sub>3</sub> during the reaction.
3. The activity of Fe-based catalysts depended strongly on the interaction between the Fe metal and the support.
4. The catalytically activity of Fe<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub> was greatly improved by the addition of NiO.
